## Question 13.2.12:

### Problem Statement

A die is tossed thrice. Find the probability of getting an odd number at least once.

### Solution

#### **Given:**

We are given that the die is tossed thrice.

#### **Need to find:**

Probability of getting an odd number at least once in the three trials.

#### **Solving steps:**

The sample space for the experiment is;

$$S = \{1, 2, 3, 4, 5, 6\}$$

Required probability of at least one odd observation is equivalent to the probability of non occurrence for all observations being even.

Let

$P(A) = \text{Probability of all observations being even}$

and

$P(B) = \text{Probability of atleast one observation being odd}$

$$\Rightarrow P(B) = 1 - P(A)$$

Possible even observations are;

$$S_{\text{even}} = \{2, 4, 6\}$$

Probability of an observation being even is;

$$p = \frac{3}{6} = \frac{1}{2}$$

Probability of all three observation being even is;

$$P(A) = \frac{1}{2} * \frac{1}{2} * \frac{1}{2} = \frac{1}{8}$$

Therefore, probability of at least one odd observation is;

$$P(B) = 1 - P(A) = 1 - \frac{1}{8} = \frac{7}{8}$$

### Conclusion

The probability of getting an odd number at least once is 0.875 as also calculated using the python code. [1]
